# Robots and Their Environment

2

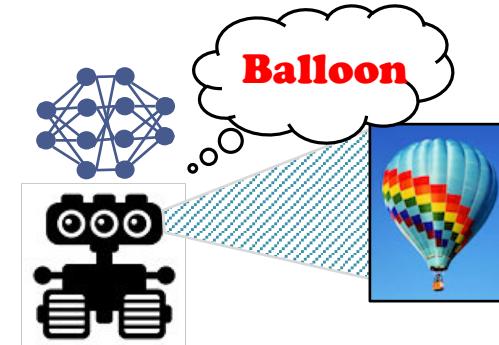

- ▶ Robots need to process lots of raw data in their environment.
  - ▶ Visual, Sounds, Temperature, ...
  - ▶ They need to understand it, to act upon it
  - ▶ For instance:
    - ▶ Drones that study an area after a disaster
    - ▶ Smart security system with lots of cameras
    - ▶ Swarm robots

# Deep Learning (DL) and Robots

3

- ▶ How they should process complex raw data?
  - ▶ Use **deep learning!**
  - ▶ It can help in many tasks:
    - ▶ Object detection
    - ▶ Scene recognition
    - ▶ Action recognition
    - ▶ Speech recognition

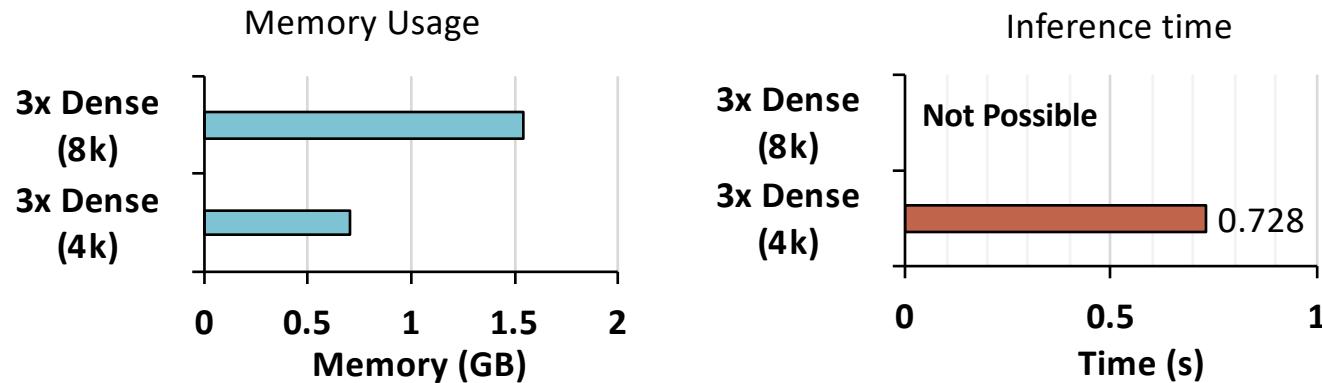

# DL Computation is Heavy

4

- ▶ But DL models are computationally intensive and resource hungry specially for cheap robots.

An example of 3x dense layers on resource constrained device:

# DL Computation is Heavy

5

- ▶ But DL models are computationally intensive.
- An example:
- It is difficult to execute DL models on all kinds of robots because:

  - 1) Usually good models have large memory footprint.
  - 2) For a robot, latency for single inference is important.

# DL Computation is Heavy

6

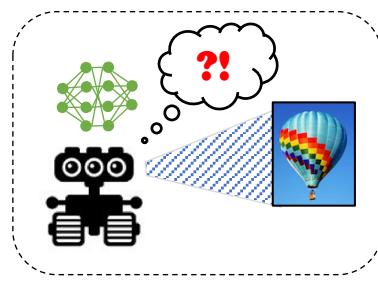

- ▶ So robots need the result fast and in **real time!**
- ▶ Then how resource-constrained robots can use DL to understand their surroundings?

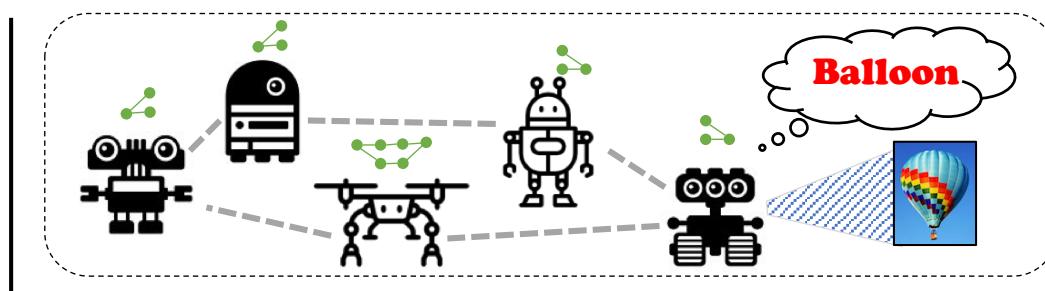

# Let's Collaborate

7

- ▶ Usually, many cheap robots share their environment.
- ▶ Not all robots need to perform computations at same time.
- ▶ So What if they share their knowledge and help each other?

**(a) Single Robot**

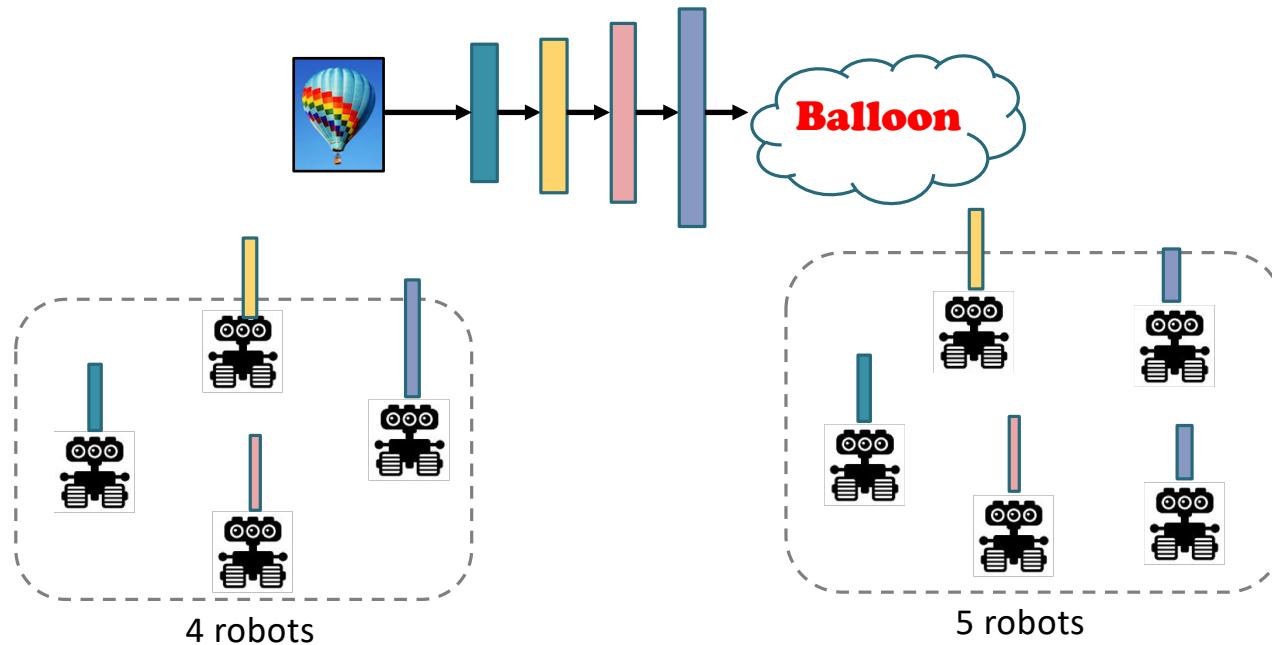

**(b) Collaborative Robots**

# Our Work Overview

8

- ▶ We have proposed a technique to efficiently distribute DNN-based recognition.

Distributed Perception by Collaborative Robots

IROS 2018

 Georgia Tech  comparch

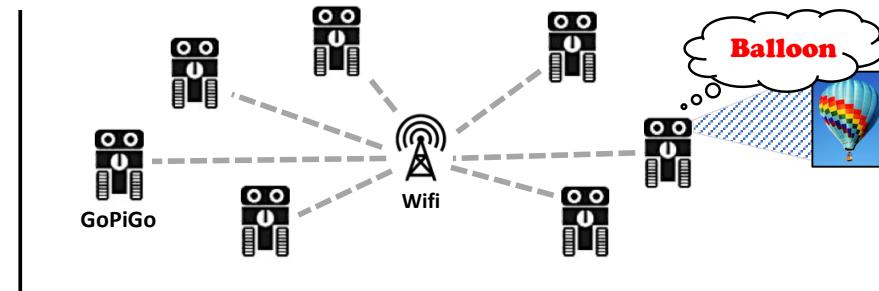

# Our Work Overview

9

- ▶ We proposed an algorithm for deploying the distributed robot system only with **Raspberry Pis**.

(a) GoPiGo Robot

(b) Our Distributed Robot System

- ▶ We used AlexNet, VGG16, and a video recognition model as example models.

# Outline

Introduction & Motivation

**Data and Model Parallelism**

▶ Fully Connected and Conv Layers

Distributing DNN

▶ Algorithm

System Evaluations

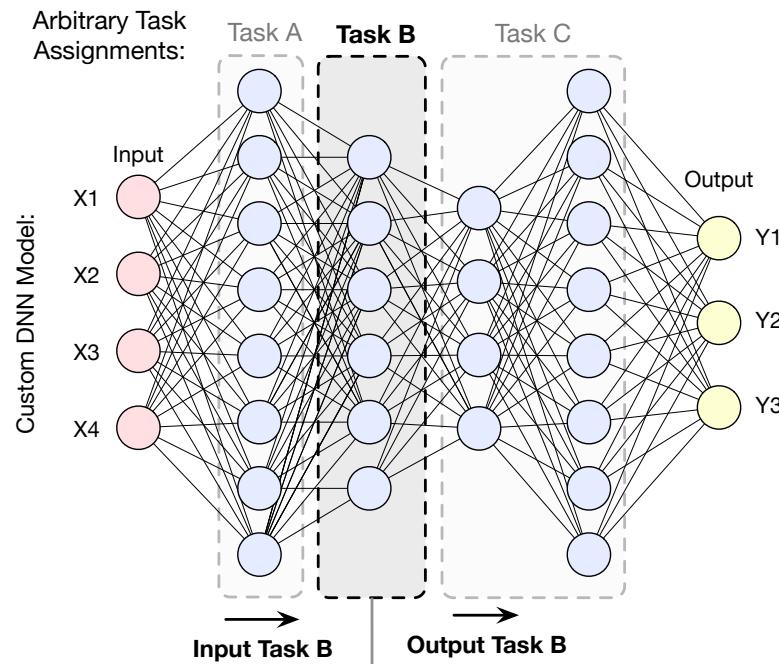

Conclusions

# Model & Data Parallelism

11

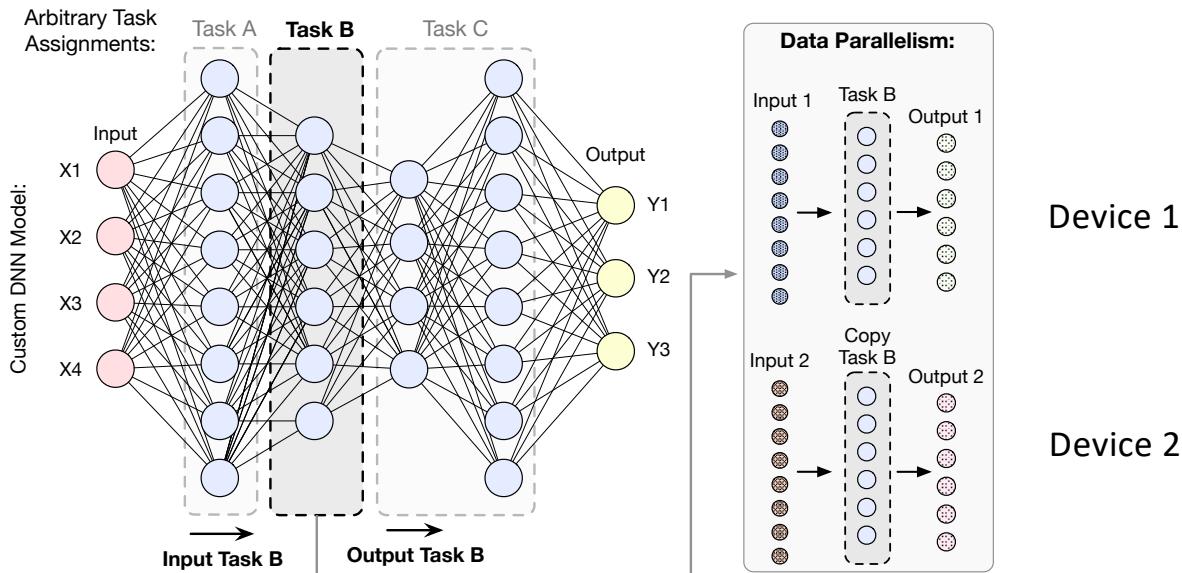

Assume a custom DNN model, divided layer by layer:

# Data Parallelism

12

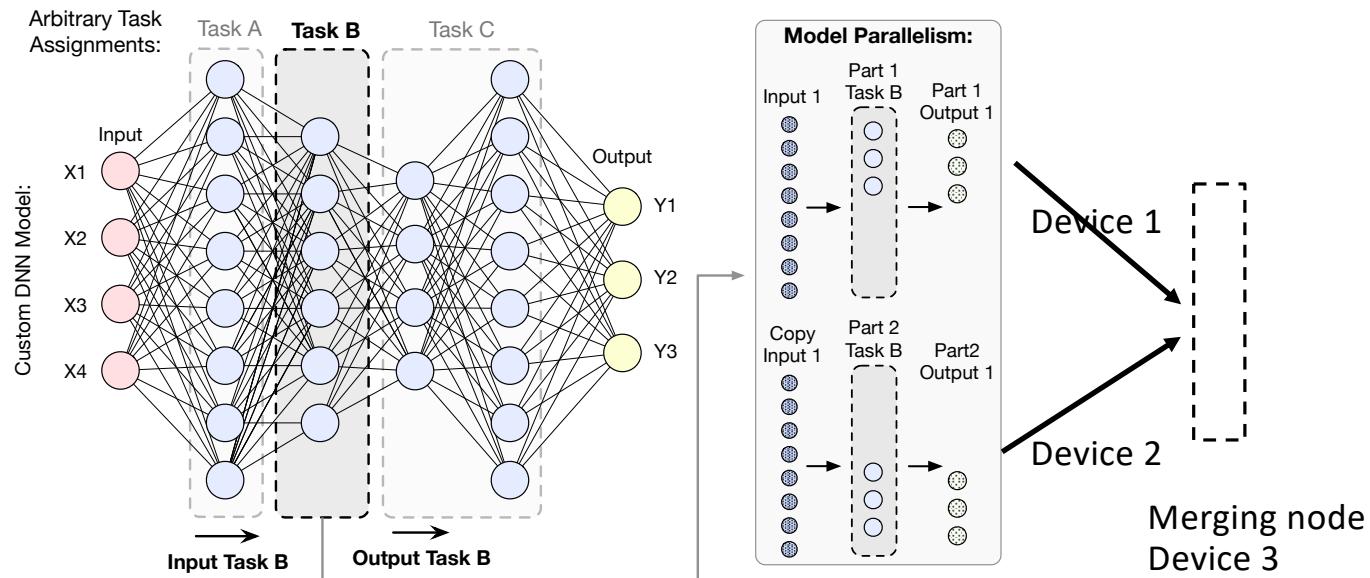

Data parallelism is providing the next input to multiple devices in a network.

# Model Parallelism

13

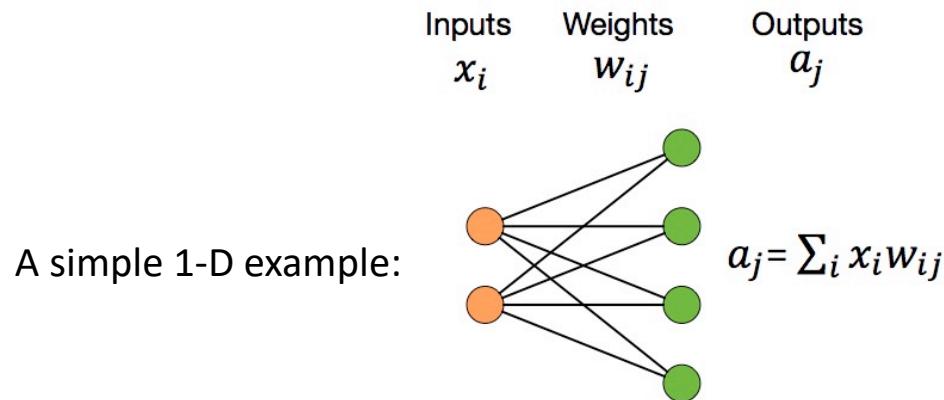

Model parallelism is splitting parts of a given layer or group of layers over multiple devices.

# Fully Connected (FC) Layer

14

- ▶ Every output element is a summation of weighted inputs
- ▶ Each output element have its own set of weights
- ▶ A matrix multiplication

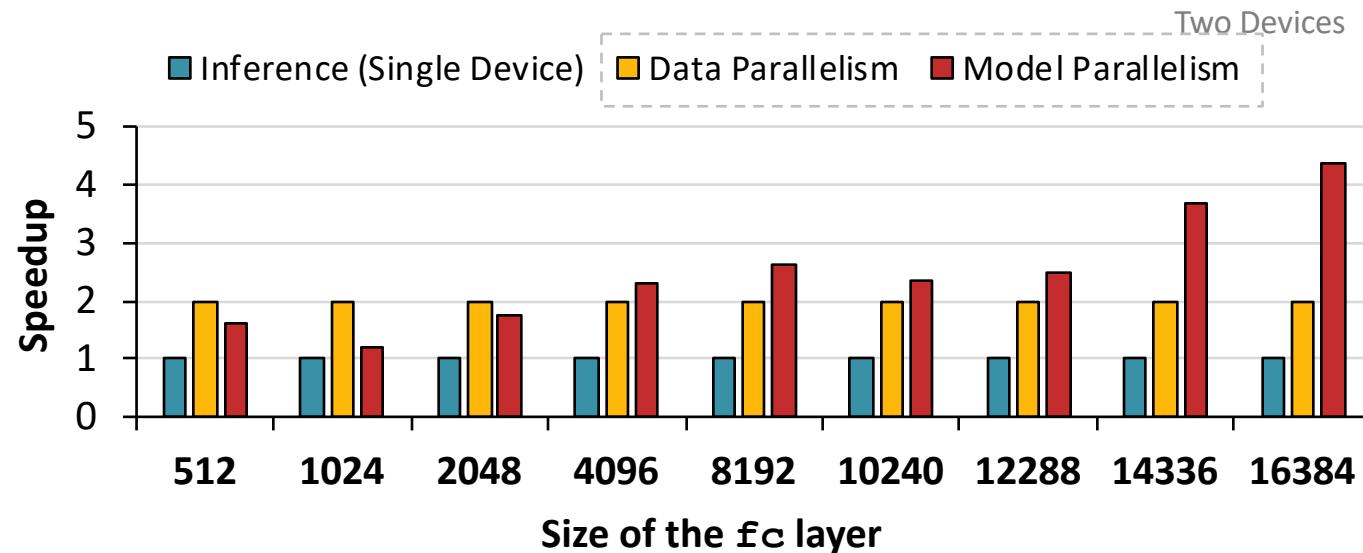

# Model & Data Parallelism for FC

15

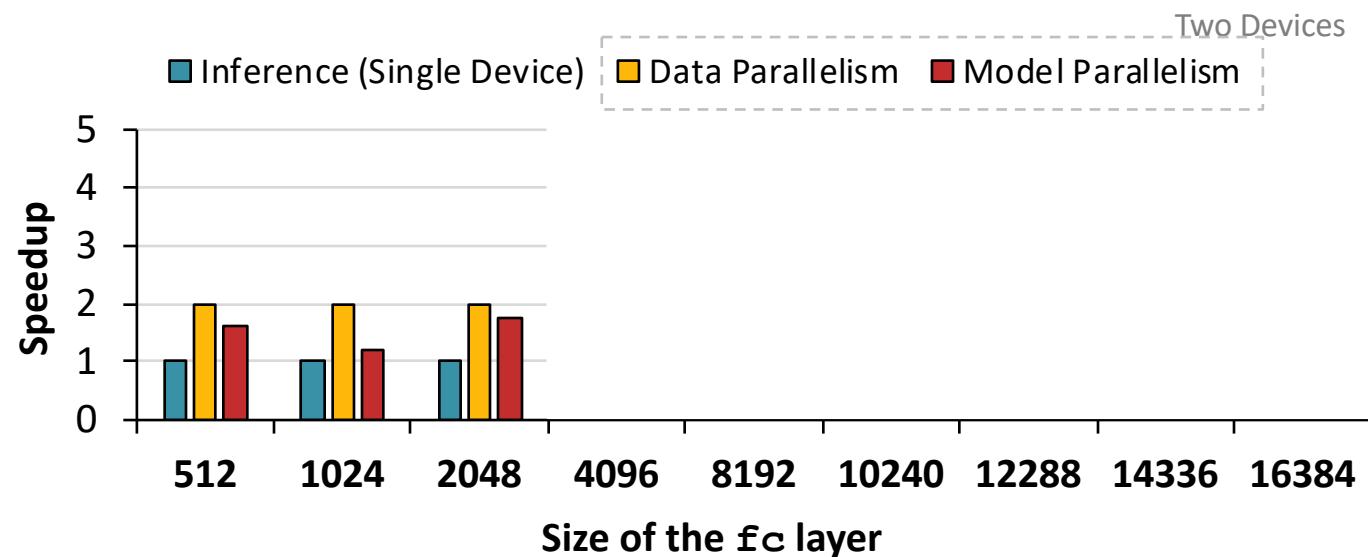

- ▶ Every output element is a summation of weighted inputs
- ▶ Each output element have its own set of weights
- ▶ A matrix multiplication

# Model & Data Parallelism for FC

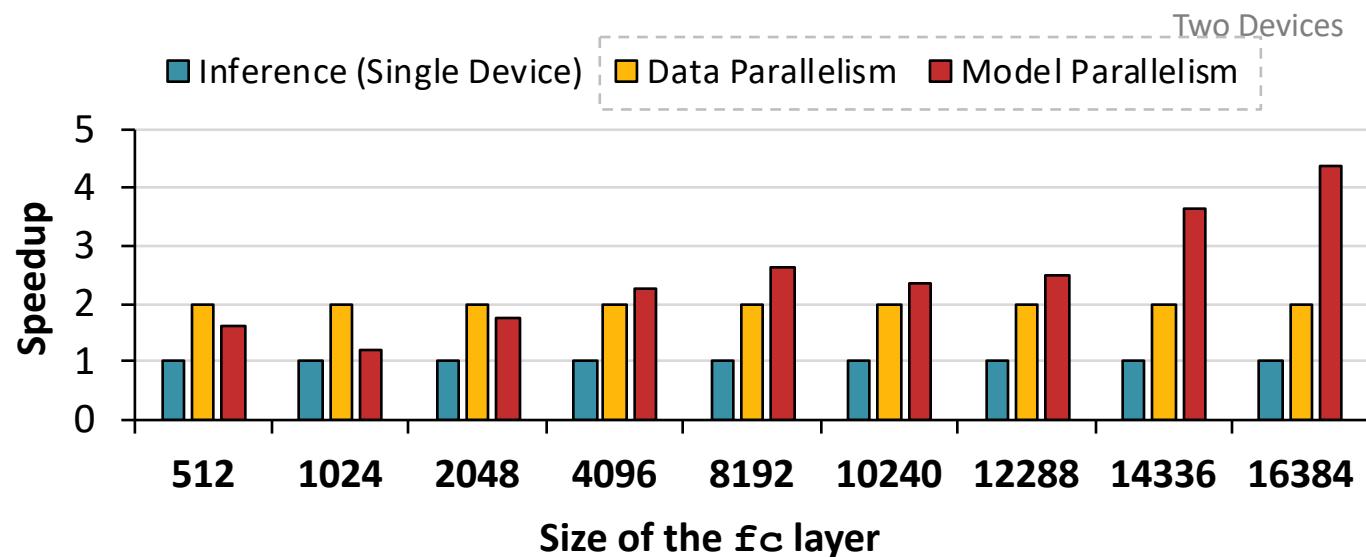

16

# Model & Data Parallelism for FC

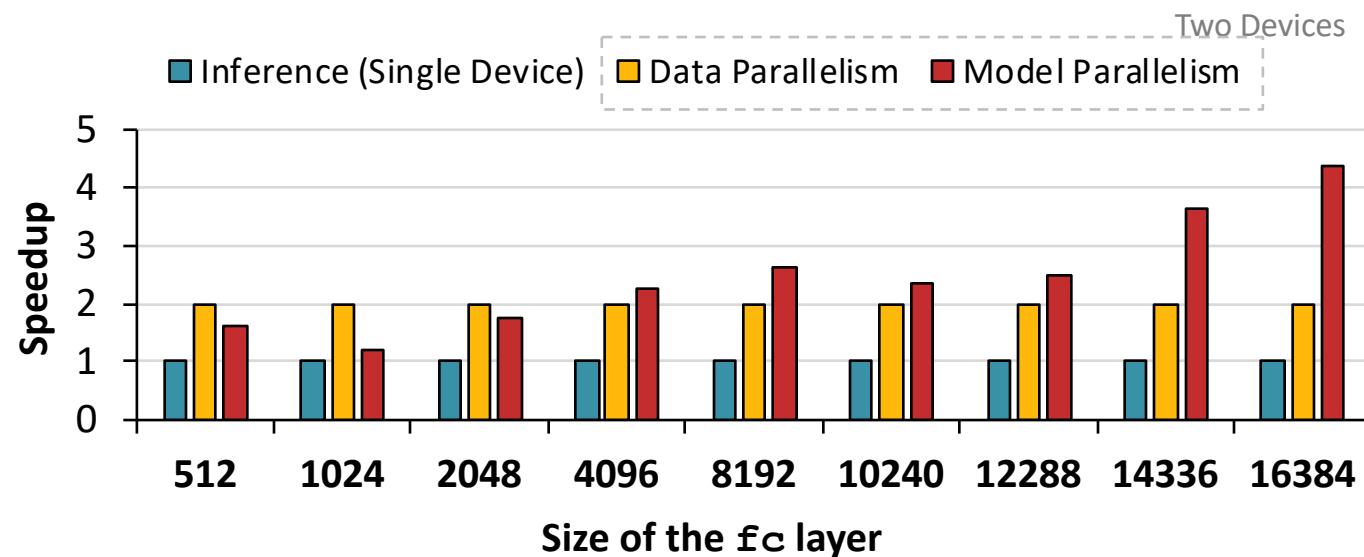

17

# Model & Data Parallelism for FC

18

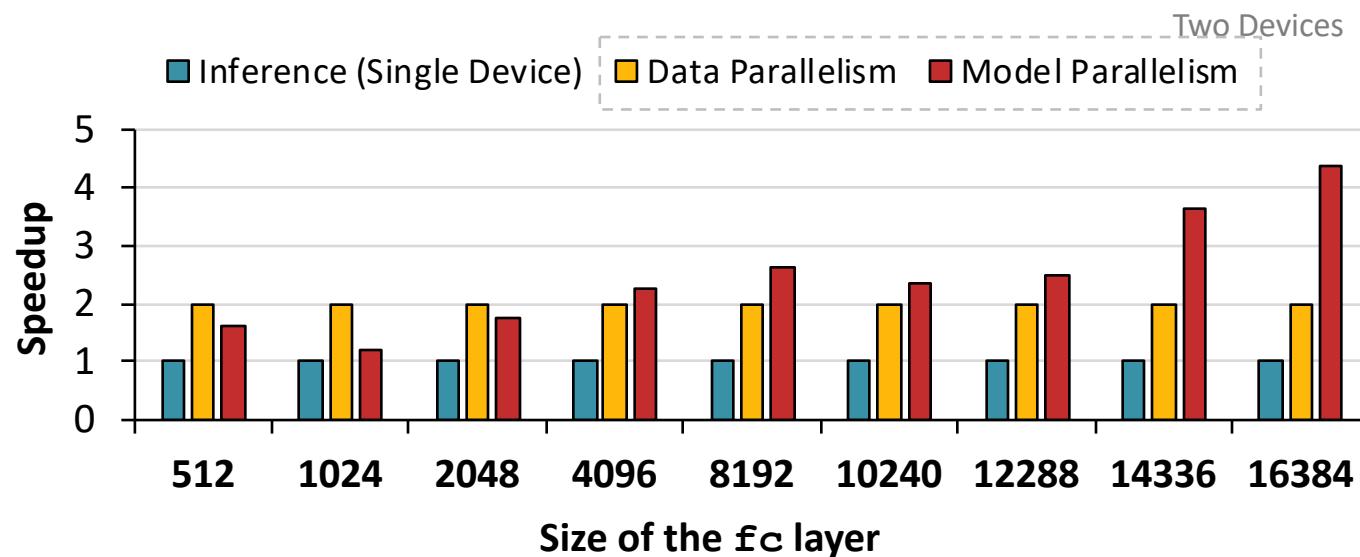

Model parallelism reduces memory footprints.  
So, we avoid slow hard drive accesses

# Model & Data Parallelism for FC

19

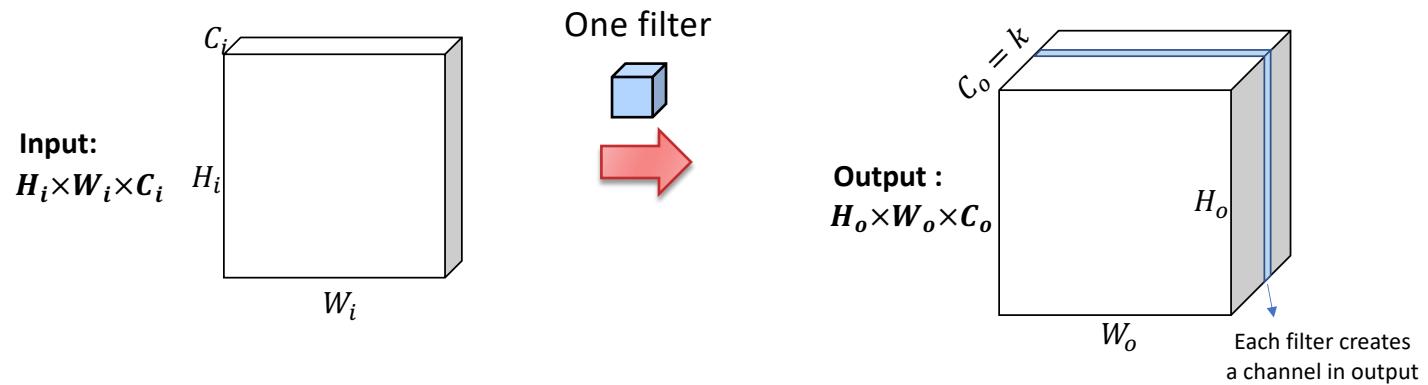

**Fully Connected Layers:** Either data or model parallelism depending on size of the layer, input, and memory

# Convolution Layer

20

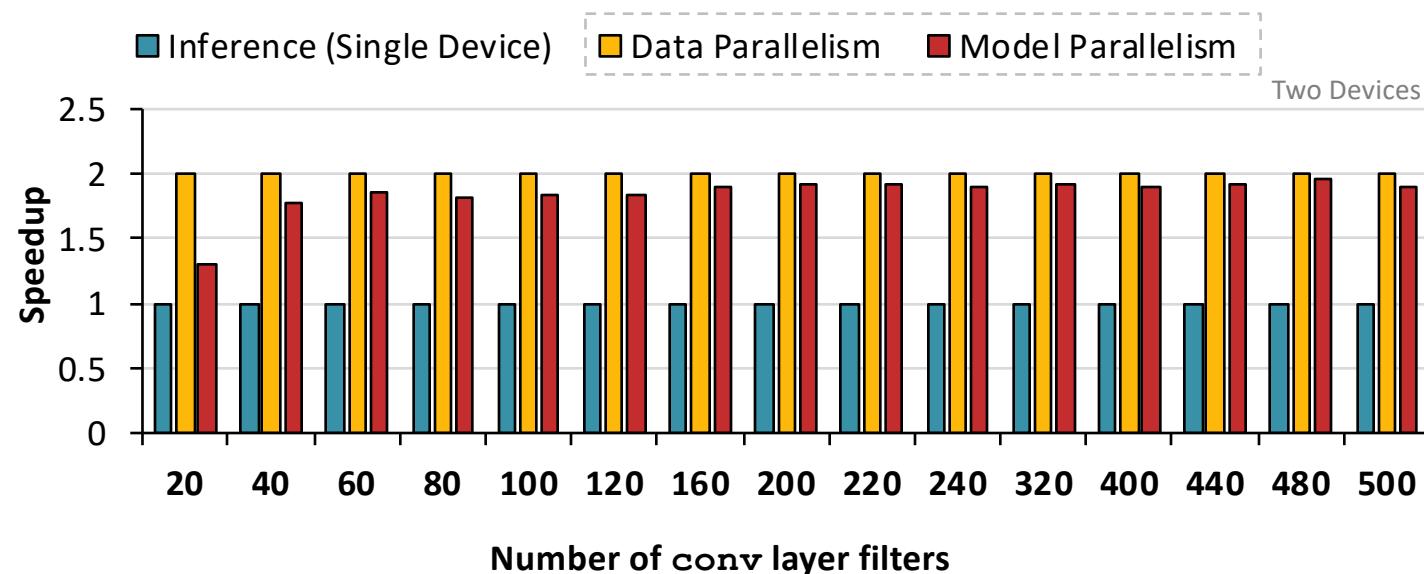

- ▶ Every channel in the output is derived from applying the **same** filter on the input
- ▶ Memory footprint size is smaller → fit into device memory size
- ▶ Model parallelism: split based on filters, and one more merging node at the end

# Model & Data Parallelism for Conv

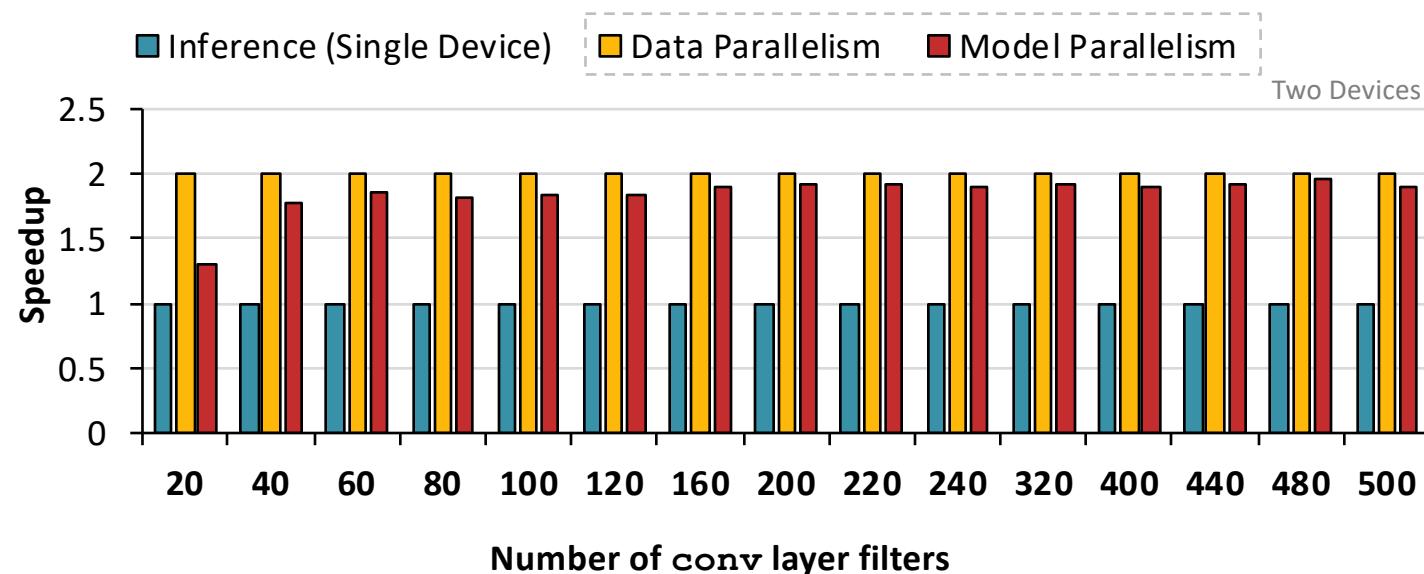

21

Conclusions

# Software & Hardware

26

## Software:

- ▶ Keras 2.1
  - ▶ With Tensorflow backend for Raspberry Pis
  - ▶ With Tensorflow-GPU backend for TX2
- ▶ Apache Avro for procedure call (RPC) and data serialization

# Hardware Overview

27

## Raspberry PI 3:

- ▶ Cheap and accessible platform
- ▶ Connected via a Wifi router
- ▶ No GPU
- ▶ \$40

## Nvidia Jetson TX2:

- ▶ High-end embedded platform
- ▶ Has a GPU
- ▶ \$600

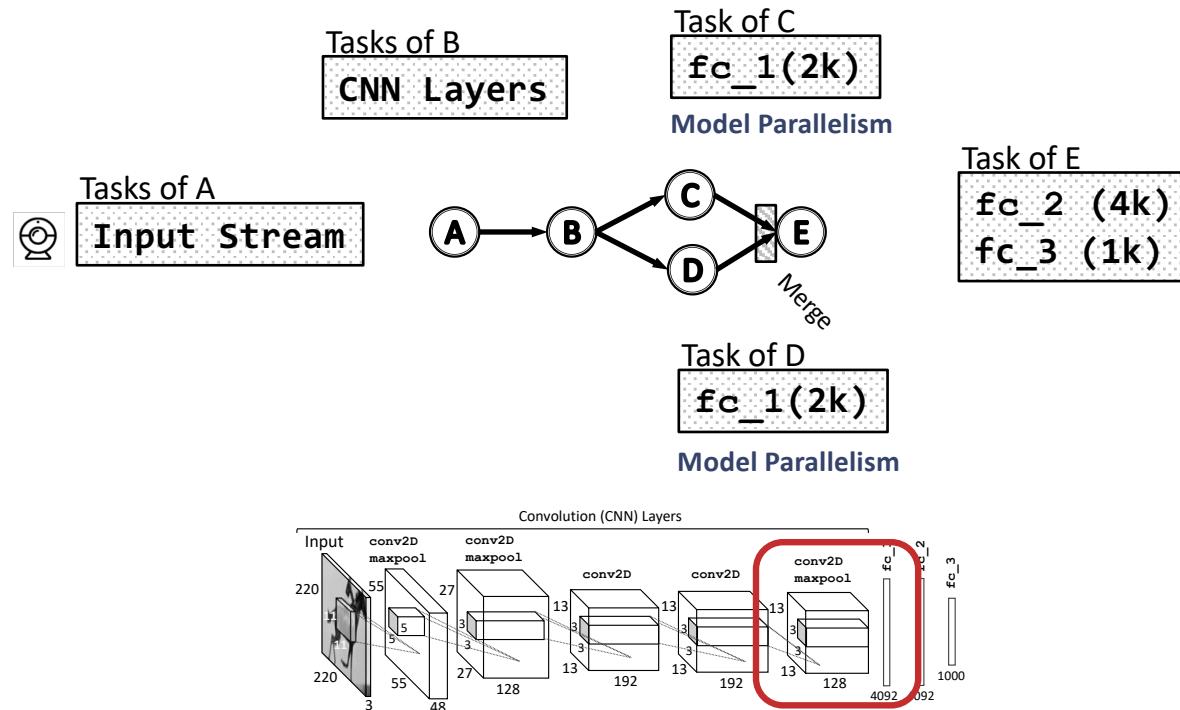

Moreover, we measured whole system power with a power analyzer

# AlexNet Distribution I

28

Five-device system:

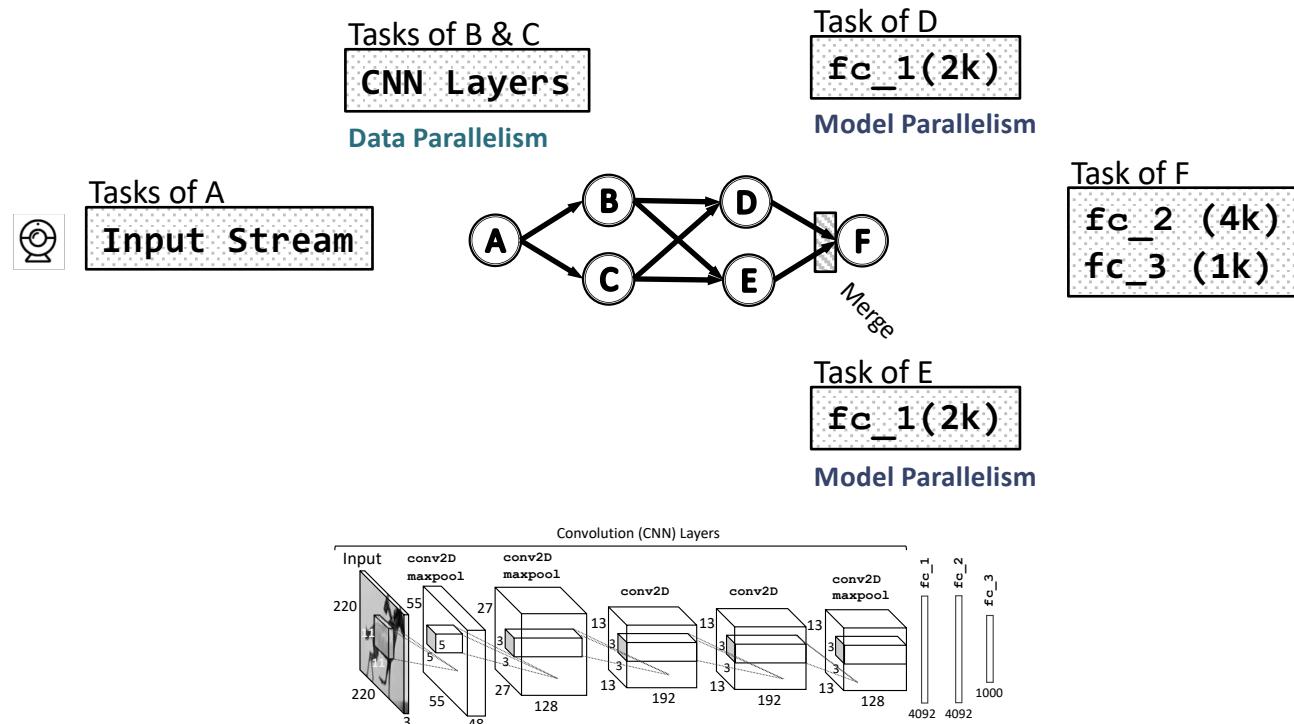

# AlexNet Distribution II

29

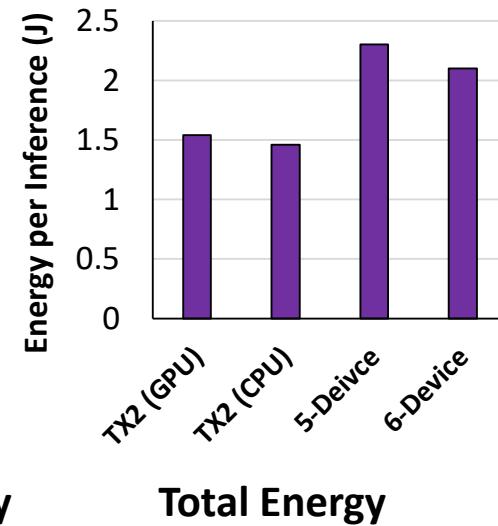

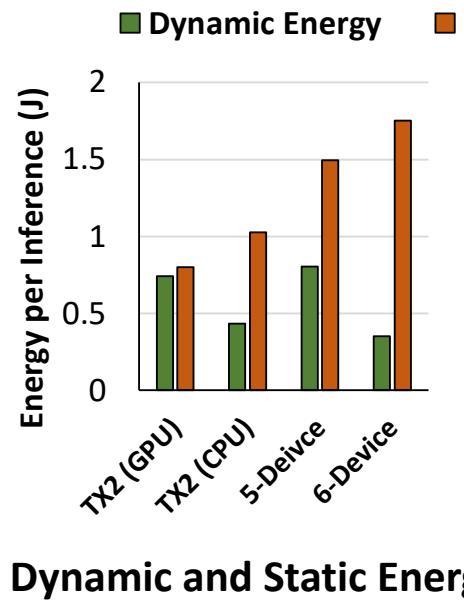

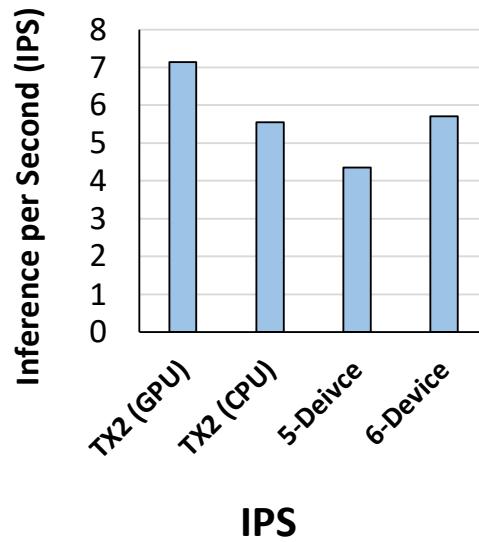

Six-device system:

30

# AlexNet Results

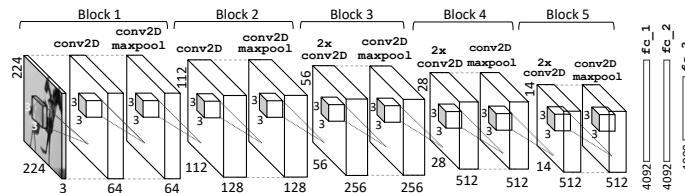

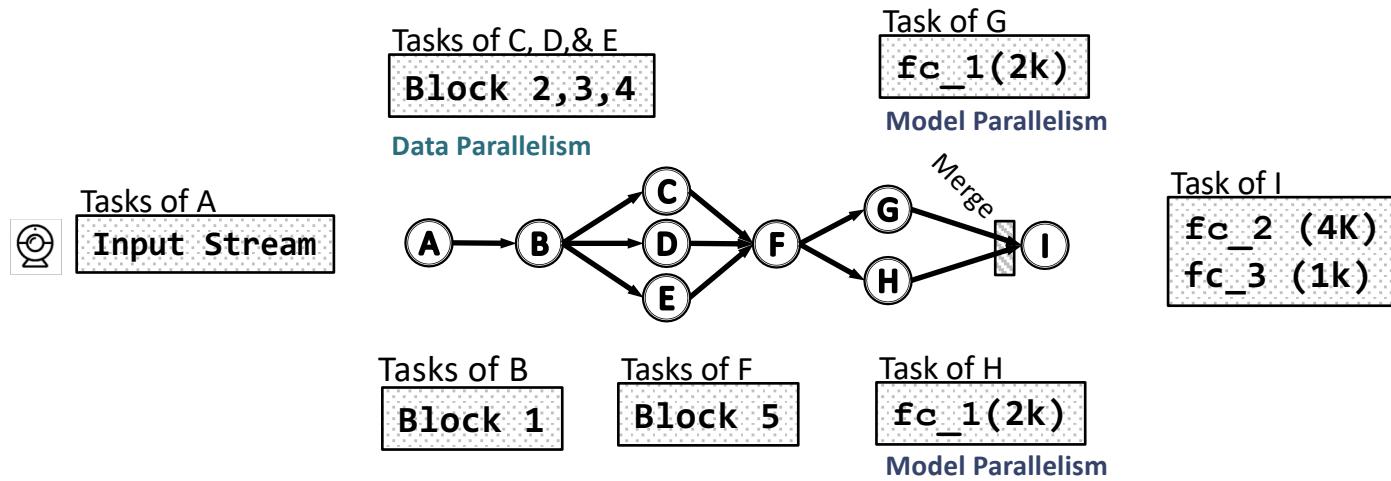

Comparable IPS with TX2 (-30%)  
Lower dynamic energy consumption

# VGG16 Distribution I

31

Nine-device system:

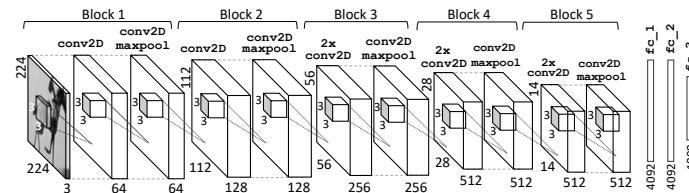

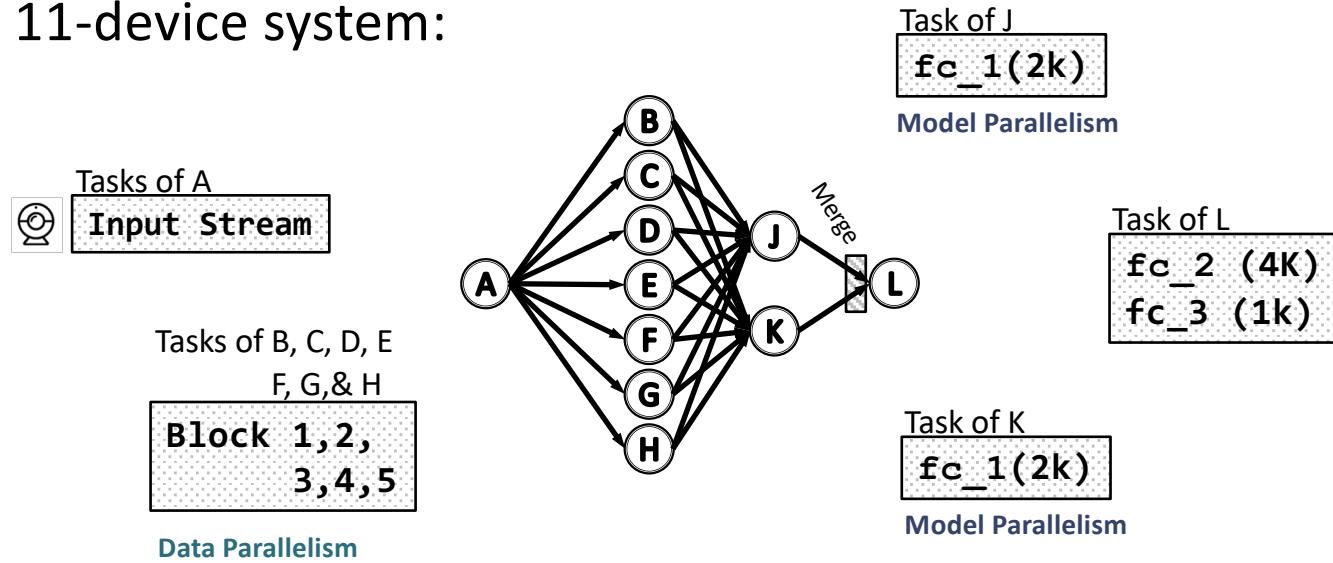

# VGG16 Distribution II

32

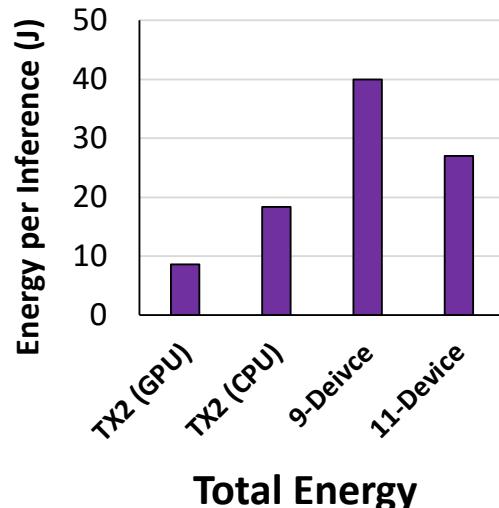

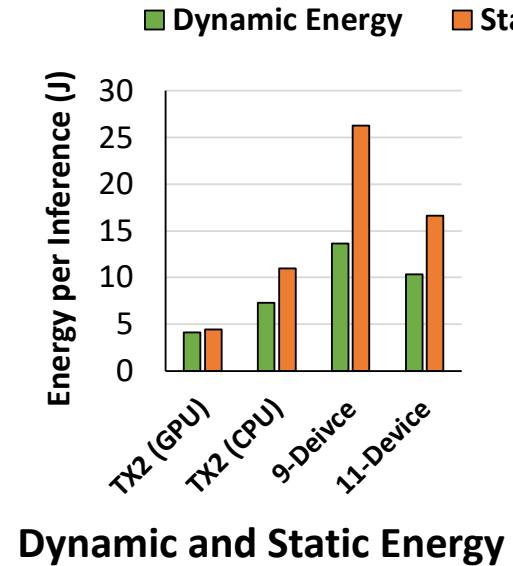

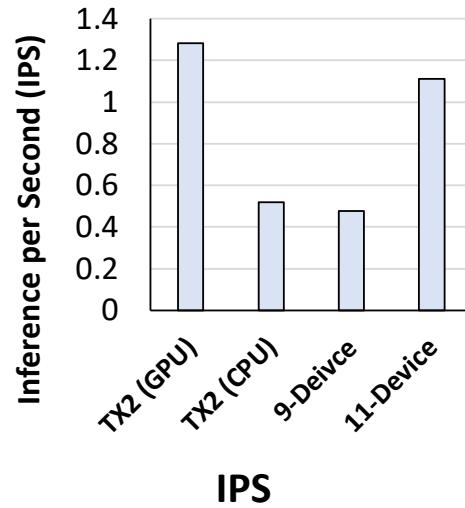

11-device system:

# VGG16 Results

33

Comparable IPS with TX2 (-15%)  
We achieve 2.3x speedup, by reassigning CNN blocks

System Evaluations

**Conclusions**

# Conclusions

35

- ▶ We used a farm of Raspberry PIs for DNN processing
- ▶ Our technique achieves acceptable real-time performance
  - ▶ Compared to TX2 CPU, we achieve similar performance with 6 robots for AlexNet
  - ▶ 11 robots for VGG-16 compared to TX2 GPU

## Future Work:

- ▶ Study the robustness of such systems
- ▶ Apply our technique to more DNN models
- ▶ Implement our model on distributed robot systems

# Layers of ML Models

39

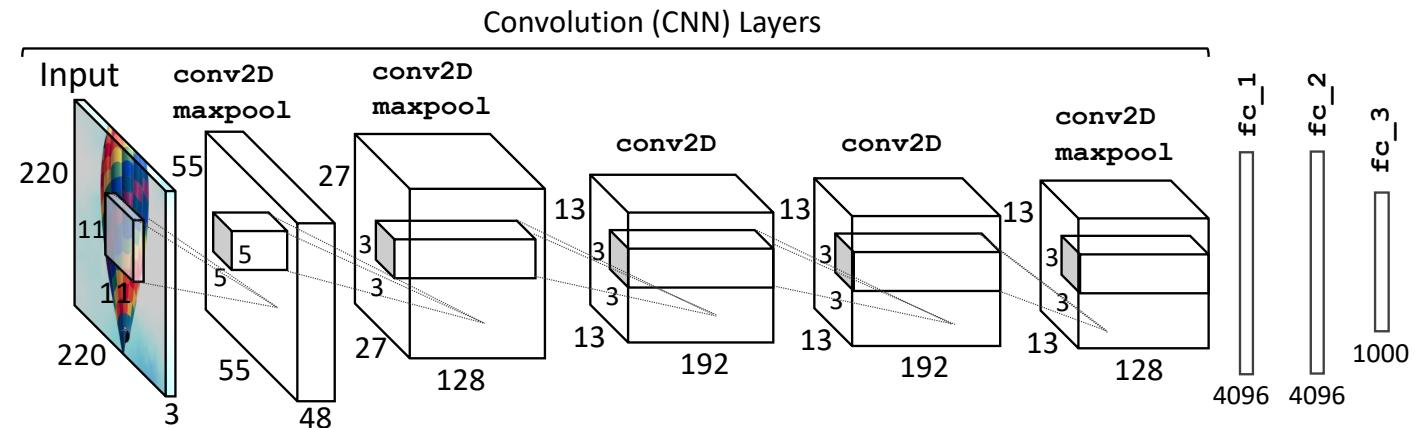

- ▶ Convolution: Applies several filters to the input
  - ▶ Compute bound, more locality
- ▶ Activation: Introduces non-linearity
  - ▶ e.g., ReLU  $f(x) = \max(0, x)$ , not compute intensive
- ▶ Fully Connected (Dense)
  - ▶ i.e., matrix multiplication, bandwidth bound
- ▶ Pooling
  - ▶ Reduces dimensions, simple doing max, average, and ... on a subset of input

---

**Algorithm 1** Task Assignment Algorithm.

---

```
1: function TASKASSIGNMENT( $dnn, n_{max}, comm, mem_{size}$ )
   Inputs:  $dnn$ : DNN model in form of layers[type, size,  $input_{size}$ ,  $\beta$ ]
             $n_{max}$ : Maximum number of the devices
             $comm$ : Communication overhead model ( $comm(size_{data})$ )
             $mem_{size}$ : Device memory size
2:    $L := \text{EXTRACT\_MODEL\_TO\_LAYERS}(dnn)$ 
3:   for  $n$  from 1 to  $n_{max}$ : do
4:      $tasks_{final}[n] := \emptyset$ 
5:     for  $n$  from 1 to  $n_{max}$ : do
6:        $TG, noFit := \text{FIND\_INITIAL\_TASKGROUP}(L, mem_{size})$ 
7:       if  $sizeof(TG) > n$  then
8:          $tasks[n] = \text{COMBINE\_TASKS}(TG, mem_{size}, n_{max}, n)$ 
9:       if  $sizeof(TG) = n$  then
10:         $tasks[n] = TG$ 
11:       if  $sizeof(TG) < n$  or  $noFit == \text{True}$  then
12:         while  $sizeof(TG) \neq n$  do
13:            $task_{variant} := \emptyset$ 
14:           for every  $t \in TG$ : do
15:              $[task_{variant}] += \text{PROFILED\_VARIANTS}(t, comm)$ 
16:            $task_{replaced}, task_{new} = \text{SELECT\_LOWEST}([task_{variant}])$ 
17:            $TG = TG - task_{replaced} + task_{new}$ 
18:            $tasks_{final}[n] = TG$ 
19:   return  $tasks_{final}$ 
```

# Hardware Overview

45

## Raspberry PI 3:

- ▶ Cheap and accessible platform
- ▶ Connected via a Wifi router
- ▶ No GPU
- ▶ \$40

Table 1: Raspberry PI 3 specification

CPU	1.2 GHz Quad Core ARM Cortex-A53	
Memory	900 MHz 1 GB RAM LPDDR2	
GPU	No GPGPU Capability	
Price	\$35 (Board) + \$5 (SD Card)	
Power Consumption	Idle (No Power Gating) %100 Utilization Averaged Observed	1.3 W 6.5 W 3 W

## Nvidia Jetson TX2:

- ▶ High-end embedded platform
- ▶ Has a GPU
- ▶ \$600

Table 2: Nvidia Jetson TX2 specifications

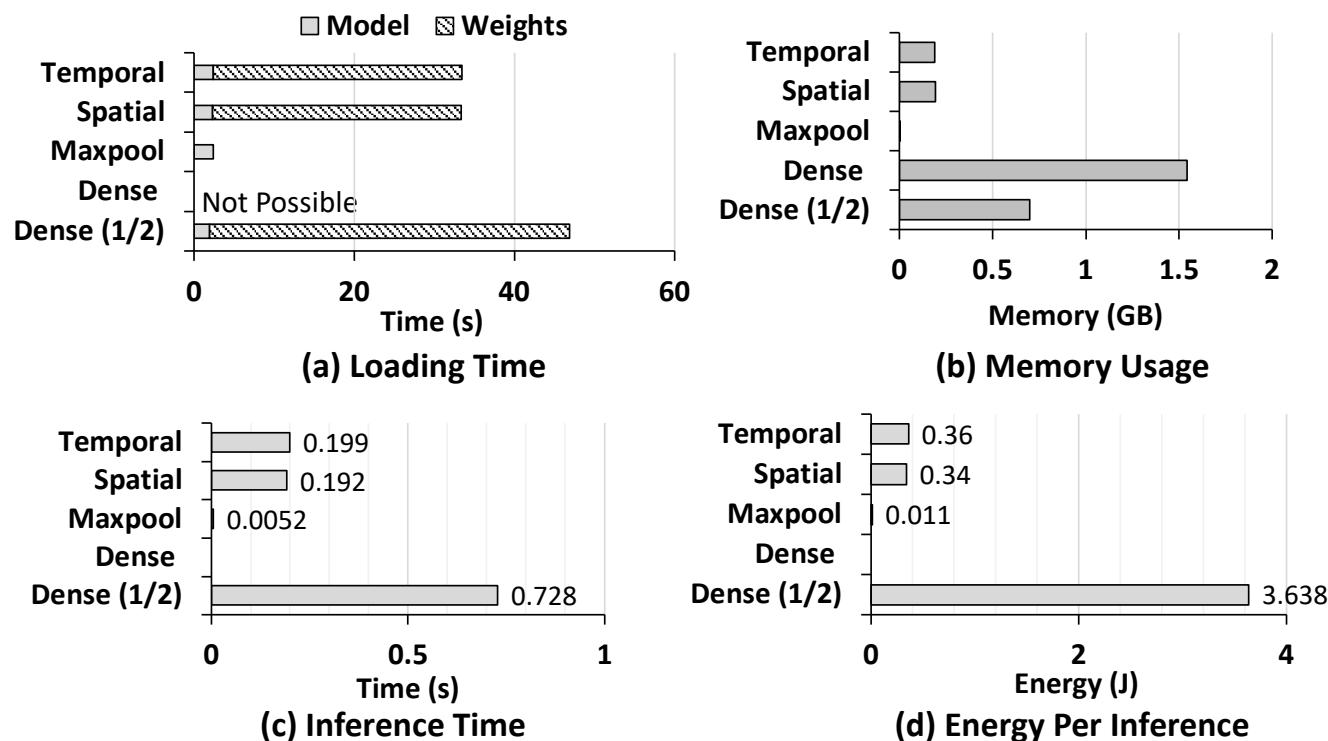

CPU	2.00 GHz Dual Denver 2 + 2.00 GHz Quad Core ARM Cortex-A57	
Memory	1600 MHz 8 GB RAM LPDDR4	
GPU	Pascal Architecture - 256 CUDA Core	
Total Price	\$600	
Power Consumption	Idle (Power Gated) %100 Utilization Averaged Observed	5 W 15 W 9.5 W

Moreover, we measured whole system power with a power analyzer
